[Received on 5 March 2017; revised on 15 July 2017]

The contribution of this article contains two parts: first, we prove a supercloseness result for the partially penalized immersed finite element (PPIFE) methods in (Lin, T., Lin, Y. & Zhang, X. (2015), Partially penalized immersed finite element methods for elliptic interface problems. SIAM J. Numer. Anal., 53, 1121–1144) and then based on the supercloseness result, we show that the gradient recovery method proposed in our previous work (Guo, H. & Yang, X. (2017) Gradient recovery for elliptic interface problem: II. Immersed finite element methods. J. Comput. Phys., 338, 606–619) can be applied to the PPIFE methods and the recovered gradient converges to the exact gradient with a superconvergent rate \( O(h^{1.5}) \). Hence, the gradient recovery method provides an asymptotically exact a posteriori error estimator for the PPIFE methods. Several numerical examples are presented to verify our theoretical results.

Keywords: superconvergence; interface problem; immersed finite element; supercloseness; gradient recovery.

1. Introduction

Recently, there has been of great interest in developing finite element method for interface problems, where the discontinuous coefficients appear naturally due to the background consisting of rather different materials (e.g., Babuška, 1970; Xu, 1982; Barrett & Elliott, 1987; Bramble & King, 1996; Chen & Zou, 1998; Li, 1998; Chen & Dai, 2002; Hansbo & Hansbo, 2002; Li et al., 2003; Hou et al., 2004; Li et al., 2004; Hou & Liu, 2005; Li & Ito, 2006; Gong et al., 2007/08; Bastian & Engwer, 2009; Cai & Zhang, 2009; Lin et al., 2015; Huang et al., 2017). It is well-known that classical finite element method works for interface problems, provided that the mesh is aligned with the interface (Babuška, 1970; Xu, 1982; Bramble & King, 1996; Chen & Zou, 1998). Such requirement may be a heavy burden, especially when the interface involves complex geometry and, therefore, it is difficult and time-consuming to generate a body-fitted mesh. To release the restriction, Li (1998) proposed an immersed finite element (IFE) method for the two-point boundary value problem. This idea was further generalized into two-dimensional cases by Li et al. (2003) who constructed a nonconforming IFE method for interface problems. The main idea of IFE is to solve the interface problems on the Cartesian mesh (uniform mesh) by modifying the basis functions near the interface.

The optimal approximation capability of IFE space was justified in Li et al. (2004). However, there is no proof for the optimal convergence of the classical IFE method in the two-dimensional setting (see Lin et al., 2015), even though numerous numerical experiments showed optimal convergence for elliptic equations. Interested readers are referred to Chou et al. (2010), He et al. (2012) and Kwak et al. (2010) for the progress of theoretical results. Moreover, the numerical test results demonstrated that classic IFE method (Ji et al., 2014) achieves only the first-order convergence in the $L^\infty$ norm. In fact, the error function $|u - u_h|$ has relatively larger values over the interfaces due to the discontinuities of both the trial and the test functions. To eliminate this disadvantage, the authors of Ji et al. (2014) added a correction term into the bilinear form of the classic IFE method, and the authors of Hou & Liu (2005) and Hou et al. (2013, 2004) proposed a new IFE formulation in the framework of the Petrov–Galerkin method, where the test function may not be the trial function. However, the theoretical foundation of their methods is not fully established. Alternatively, Lin et al. (2015) proposed PPIFE methods to penalize the inter-element discontinuity. Thanks to the added penalty term, the authors proved the coercivity of the bilinear form and showed the optimal convergence in the energy norm.

Superconvergence is an active research topic in the finite element community, and its theory for smooth problems is well established (see, e.g., Zhu & Lin, 1989; Zienkiewicz & Zhu, 1992a,b; Wahlbin, 1995; Lin & Yan, 1996; Lakhany et al., 2000; Babuška & Strouboulis, 2001; Chen, 2001; Bank & Xu, 2003; Naga & Zhang, 2004; Xu & Zhang, 2004; Naga & Zhang, 2005; Zhang & Naga, 2005; Chen & Xu, 2007; Wu & Zhang, 2007; Guo & Zhang, 2015; Guo et al., 2017, and references therein). On the other hand, however, the superconvergence phenomenon for interface problems is not yet well understood due to discontinuing of the coefficient crossing the interface. In Wei et al. (2014), a supercloseness result between the linear finite element solution and the linear interpolation of the exact solution is proved for a two-dimensional interface problem with a body-fitted mesh. Recently, the first two authors proposed an improved polynomial preserving recovery (IPPR) for interface problem, and proved the superconvergence on both mildly unstructured mesh and adaptively refined mesh (Guo & Yang, 2016). For IFE method, Chou et al. introduced two special interpolation formula to recover flux more accurately for the one-dimensional linear and quadratic IFE elements (Chou, 2012; Chou & Attanayake, 2017). Cao et al. (2017) investigated the nodal superconvergence phenomena using generalized orthogonal polynomial in the one-dimensional setting. For the two-dimensional case, the first two authors proposed a new gradient recovery technique (Guo & Yang, 2017) for symmetric and consistent IFE method (Ji et al., 2014) and Petrov–Galerkin IFE method (Hou & Liu, 2005; Hou et al., 2004, 2013) and numerically verified its superconvergence. In addition, Guo & Yang (2017) numerically showed supercloseness results for both symmetric and consistent IFE method and Petrov–Galerkin IFE method.

The main goal of this work is to establish a complete superconvergence theory for the PPIFE method (Lin et al., 2015). Our analysis relies on the following three key observations: (1) the solution is piecewise smooth on each sub-domain despite its low global regularity; (2) the basis functions on noninterface elements are just basis functions for the standard linear finite element method; (3) the number of interface elements is roughly $O(h^{-1})$. The above three observations motivate us to divide the elements into the following three disjoint types: interior elements, exterior elements and interface elements. We can obtain the supercloseness using well-known results in Bank & Xu (2003), Chen & Xu (2007) and Xu & Zhang (2004) on the interior and exterior elements, respectively. In addition, the trace inequalities for the IFE functions in Lin et al. (2015) and the third observation enables us to establish $O(h^{1.5})$ supercloseness result for interface elements. Our supercloseness result reduces to the standard one as in Bank & Xu (2003), Chen & Xu (2007) and Xu & Zhang (2004) when the discontinuity disappears. It is consistent with the fact that the IFE methods become the standard linear finite element method when the discontinuity disappears. Furthermore, we show that the gradient recovery method in Guo & Yang (2017) can also be
applied to the PPIFE methods. The recovered gradient is proved to be superconvergent with the exact gradient of the interface problem and, therefore, it provides an asymptotically exact \textit{a posteriori} error estimator for PPIFE methods.

The rest of the article is organized as follows. In Section 2, we introduce the model interface problem and the PPIFE methods. In Section 3, we, first, establish the supercloseness between gradients of the PPIFE solution and the exact solution to the interface problem, and then based on the supercloseness, we prove that the recovered gradient using the method in Guo & Yang (2017) is superconvergent to the exact gradient and, hence, provides an asymptotically exact \textit{a posteriori} error estimator for PPIFE methods. In Section 4, we present some numerical experiments to support our theoretical results. Finally, we make some conclusive remarks in Section 5.

2. Preliminary

In this section, we shall introduce the elliptic interface problem and its discrete form using the PPIFE methods (Lin et al., 2015).

2.1 Elliptic interface problem

Let $\Omega$ be a bounded polygonal domain with Lipschitz boundary $\partial \Omega$ in $\mathbb{R}^2$. A $C^2$-curve $\Gamma$ divides $\Omega$ into two disjoint sub-domains $\Omega^-$ and $\Omega^+$, which is typically characterized by zero level set of some level set function $\phi$ (Sethian, 1996; Osher & Fedkiw, 2003), with $\Omega^- = \{z \in \Omega | \phi(z) < 0\}$ and $\Omega^+ = \{z \in \Omega | \phi(z) > 0\}$. We shall consider the following elliptic interface problem

\begin{align*}
-\nabla \cdot (\beta(z) \nabla u(z)) &= f(z), \quad z \text{ in } \Omega \setminus \Gamma, \\
u &= 0, \quad z \text{ on } \partial \Omega,
\end{align*}

where the diffusion coefficient $\beta(z) \geq \beta_0$ is a piecewise smooth function, i.e.,

$$\beta(z) = \begin{cases} 
\beta^-(z) & \text{if } z \in \Omega^-, \\
\beta^+(z) & \text{if } z \in \Omega^+,
\end{cases}$$

which has a finite jump of function values across the interface $\Gamma$. At the interface $\Gamma$, one has the following homogeneous jump conditions:

\begin{align*}
[u]_\Gamma &= u^+ - u^- = 0, \\
[\beta u_n]_\Gamma &= \beta^+ u^+_n - \beta^- u^-_n = 0,
\end{align*}

where $u_n$ denotes the normal flux $\nabla u \cdot n$ with $n$ as the unit outer normal vector of the interface $\Gamma$.

In this article, we use the standard notations for Sobolev spaces and their associate norms given in Brenner & Scott (2008), Ciarlet (2002) and Evans (2010). For a subdomain $A$ of $\Omega$, let $\mathbb{P}_m(A)$ be the space of polynomials of degree less than or equal to $m$ in $A$ and $n_m$ be the dimension of $\mathbb{P}_m(A)$, which equals to $\frac{1}{2}(m + 1)(m + 2)$. $W^{k,p}(A)$ denotes the Sobolev space with norm $\| \cdot \|_{k,p,A}$ and seminorm $| \cdot |_{k,p,A}$. When $p = 2$, $W^{k,2}(A)$ is simply denoted by $H^k(A)$ and the subscript $p$ is omitted in its associate norm and seminorm. As in Wei et al. (2014), we denote $W^{k,p}(\Omega^- \cup \Omega^+)$ as the function space consisting of
piecewise Sobolev function $w$, such that $w|_{\Omega^{-}} \in W^{k,p}(\Omega^{-})$ and $w|_{\Omega^{+}} \in W^{k,p}(\Omega^{+})$. For the function space $W^{k,p}(\Omega^{-} \cup \Omega^{+})$, we define norm as

$$\|w\|_{k,p,\Omega^{-} \cup \Omega^{+}} = \left( \|w\|_{k,p,\Omega^{-}}^{p} + \|w\|_{k,p,\Omega^{+}}^{p} \right)^{1/p}$$

and seminorm as

$$|w|_{k,p,\Omega^{-} \cup \Omega^{+}} = \left( |w|_{k,p,\Omega^{-}}^{p} + |w|_{k,p,\Omega^{+}}^{p} \right)^{1/p}.$$  

We assume that $T_h$ is a shape-regular triangulation of $\Omega$ with $h = \max_{T \in T} \text{diam}(T)$ and that $h$ is small enough so that the interface $\Gamma$ never crosses any edge of $T_h$ more than once. The elements of $T_h$ can be divided into two categories: regular elements and interface elements. We call an element $T$ interface element if the interface $\Gamma$ passes the interior of $T$; otherwise, we call it regular element. If $\Gamma$ passes two vertices of an element $T$, we treat the element $T$ as a regular element. Let $T_h'$ and $T_h''$ denote the set of all interface elements and regular elements, respectively.

Let $N_h$ and $E_h$ denote the set of all vertices and interior edges of $T_h$, respectively. We can divide $E_h$ into two categories: interface edge $E_h^i$ and regular edge $E_h^r$, which are defined by

$$E_h^i = \{ e \in E_h : e \cap \Gamma \neq \emptyset \}, \quad E_h^r = E_h \setminus E_h^i. \quad (2.6)$$

For any interior edge $e$, there exist two triangles $T_{e,1}$ and $T_{e,2}$, such that $T_{e,1} \cap T_{e,2} = e$. Denote $n_e$ as the unit normal of $e$ pointing from $T_1$ to $T_2$ and define

$$\{u\} = \frac{1}{2} (u|_{T_{e,1}} + u|_{T_{e,2}}), \quad (2.7)$$

$$[u] = u|_{T_{e,1}} - u|_{T_{e,2}}. \quad (2.8)$$

When no confusion arises, the subscript $e$ can be dropped. We also introduce two special function spaces $X_h$ and $X_{h,0}$ as

$$X_h := \left\{ v \in L^2(\Omega) : v|_{T} \in H^1(T), v \text{ is continuous at } N_h \text{ and across } E_h^r \right\}, \quad (2.9)$$

$$X_{h,0} = \{ v \in X_h : v(z) = 0 \text{ for all } z \in N_h \cap \partial \Omega \}. \quad (2.10)$$

We define a bilinear form $a_h : X_{h,0} \times X_{h,0} \rightarrow \mathbb{R}$ as

$$a_h(v,w) = \sum_{T \in T_h} \int_{T} \beta \nabla v \cdot \nabla w \, dx - \sum_{e \in E_h} \int_{e} \{ \beta \nabla v \cdot n_e \} [w] \, ds$$

$$+ \varepsilon \sum_{e \in E_h} \int_{e} \{ \beta \nabla w \cdot n_e \} [v] \, ds + \sum_{e \in E_h} \int_{e} \sigma^0_{\varepsilon} [v] [w] \, ds, \quad (2.11)$$

where the parameter $\sigma^0_{\varepsilon}$ is positive and the parameter $\varepsilon$ can be arbitrary. Usually, $\varepsilon$ takes the value $-1, 0$ or $1$. It is easy to see that $a_h$ is symmetric if $\varepsilon = -1$, and it is nonsymmetric otherwise.
2.2 Partially penalized immersed finite element method

The key idea of partially penalized immersed finite element (PPIFE) methods (Lin et al., 2015) is to modify basis functions in interface elements to satisfy jump conditions (2.4) and (2.5). Consider a typical interface element $T$ as in Fig. 1, and let $z_4$ and $z_5$ be the intersection points between the interface $\Gamma$ and edges of the element. Connecting the line segment $z_4z_5$ forms an approximation of interface $\Gamma$ in the element $T$, denoted by $\Gamma_h|_T$. Then, the element $T$ is split into two parts: $T^-$ and $T^+$. We construct the following piecewise linear function on the interface element $T$

$$ \phi(z) = \begin{cases} \phi^+ = a^+ + b^+x + c^+y, & z = (x,y) \in T^+, \\ \phi^- = a^- + b^-x + c^-y, & z = (x,y) \in T^-, \end{cases} $$  \quad (2.13)

where the coefficients are determined by the following linear system:

$$ \phi(z_1) = V_1, \phi(z_2) = V_2, \phi(z_3) = V_3, $$  \quad (2.14)

$$ \phi^+(z_4) = \phi^-(z_4), \phi^+(z_5) = \phi^-(z_5), \beta^+ \partial_n \phi^+ = \beta^- \partial_n \phi^-, $$  \quad (2.15)

with $V_i$ being the nodal variables. The immersed finite element space $V_h$ (Li et al., 2003) is defined as

$$ V_h := \{ v \in L^2(\Omega) : v|_T \in V_h(T) \text{ and } v \text{ is continuous on } \mathcal{N}_h \}, $$  \quad (2.16)

$$ V_{h,0} = \{ v \in V_h : v(z) = 0 \text{ for all } z \in \mathcal{N}_h \cap \partial \Omega \}, $$  \quad (2.17)

The general variational form (Lin et al., 2015) of (2.1)–(2.5) is to find $u_h \in X_{h,0}$, such that

$$ a_h(u, v) = (f, v) \quad \text{for all } v \in X_{h,0}. $$  \quad (2.12)
where

\[ V_h(T) := \begin{cases} \{ v \mid v \in \mathbb{P}_1(T) \}, & \text{if } T \in T_h^r; \\ \{ v \mid v \text{ is defined by (2.13)--(2.15)} \}, & \text{if } T \in T_h^i. \end{cases} \]  

(2.18)

A function in \( V_h(T) \) is called a linear IFE function on \( T \) when \( T \) is an interface element. For the linear IFE function, traditional trace inequality (Ciarlet, 2002; Brenner & Scott, 2008) fails. Lin et al. (2015) established the following trace inequality:

**Lemma 2.1** Let \( T \) be an arbitrary interface element and \( e \) be an edge of \( T \). Then, there exists a constant \( C \) independent of the interface location and mesh size \( h \) such that the following inequality holds:

\[ \| \beta \nabla v \cdot n_e \|_{0,e} \leq Ch^{1/2}|T|^{-1/2}\sqrt{\beta} \| \nabla v \|_{0,T}, \]  

(2.19)

for every linear IFE function \( v \) on \( T \).

It is obvious that \( V_h \) (respectively \( V_{h,0} \)) is a subspace of \( X_h \) (respectively \( X_{h,0} \)). The PPIFE methods for (2.1)--(2.5) read as finding \( u_h \in V_{h,0} \) such that

\[ a_h(u_h, v_h) = (f, v_h) \quad \text{for all } v_h \in V_{h,0}. \]  

(2.20)

The energy norm \( \| \cdot \|_h \) is defined as

\[ \| v_h \|_h = \left( \sum_{T \in \mathcal{T}_h} \int_T \beta \nabla v_h \cdot \nabla v_h \, dx + \sum_{e \in \mathcal{E}_h^e} \int_e \sigma_0^\epsilon |v_h|_2^2 \, ds \right)^{1/2}. \]  

(2.21)

The following coercivity has been proved in Lin et al. (2015):

**Lemma 2.2** There exists a constant \( C > 0 \), such that

\[ C\| v_h \|_h^2 \leq a_h(v_h, v_h) \quad \text{for all } v_h \in V_{h,0} \]  

(2.22)

is true for \( \epsilon = 1 \) unconditionally and is true for \( \epsilon = 0 \) or \( \epsilon = -1 \) under the condition that \( \sigma_0^\epsilon \) is large enough.

Based on the above coercivity, Lin et al. proved the following optimal convergence result:

**Theorem 2.3** Assume that the exact solution \( u \) to the interface problem (2.1)--(2.5) is in \( H^3(\Omega^- \cup \Omega^+) \) and \( u_h \) is the solution to (2.20) on a Cartesian mesh \( \mathcal{T}_h \). Then, there exists a constant \( C \) such that

\[ \| u - u_h \|_h \leq Ch\| u \|_{3, \Omega^- \cup \Omega^+}. \]  

(2.23)
Remark 2.4 As remarked in Lin et al. (2015), when the exact solution belongs to $W^{2,\infty}(\Omega^- \cup \Omega^+)$, the IFE solution $u_h$ of (2.20) on a Cartesian mesh $T_h$ has error estimation in the following form:

$$
\|u - u_h\|_h \leq C \left( h \|u\|_{2,\Omega^- \cup \Omega^+} + h^{1.5} \|u\|_{2,\infty,\Omega^- \cup \Omega^+} \right).
$$

(2.24)

Note that the above error estimation is also an optimal one since the leading (first) term is of $O(h)$.

3. Superconvergence analysis

In this section, we first present a superconvergence analysis for the PPIFE method on shape-regular meshes. Then, we show that the gradient recovery method introduced in Guo & Yang (2017) is applicable and prove that the recovered gradient is superconvergent to the exact gradient.

3.1 Supercloseness result

From now on, we suppose $T_h$ is a shape-regular triangular mesh, although $T_h$ is usually Cartesian mesh in the literature of IFE methods. Let $h = \max_{T \in T_h} \text{diam}(T)$. The set of regular element $T'_h$ can be further decomposed into the following two disjoint parts:

$$
T^-_h := \{ T \in T'_h | T \text{ has all three vertices in } \overline{\Omega^-} \},
$$

$$
T^+_h := \{ T \in T'_h | T \text{ has all three vertices in } \overline{\Omega^+} \}. \tag{3.1}
$$

Definition 3.1

1. Two adjacent triangles are called to form an $O(h^{1+\alpha})$ approximate parallelogram if the lengths of any two opposite edges differ only by $O(h^{1+\alpha})$.

2. The triangulation $T_h$ is called to satisfy Condition $(\sigma, \alpha)$ if there exist a partition $T_h = T_{h,1} \cup T_{h,2}$ of $T_h$ and positive constants $\alpha$ and $\sigma$, such that every two adjacent triangles in $T_{h,1}$ form an $O(h^{1+\alpha})$ parallelogram and

$$
\sum_{T \in T_{h,2}} |T| = O(h^{\sigma}).
$$

Remark 3.2 It is obvious that the Cartesian mesh satisfies Condition $(\sigma, \alpha)$, with $\sigma = \infty$ and $\alpha = 1$.

Suppose $T_h$ satisfies Condition $(\sigma, \alpha)$. Then, we can prove the following supercloseness result:

Theorem 3.3 Suppose the triangulation $T_h$ satisfies Condition $(\sigma, \alpha)$. Let $u$ be the solution of the interface problem (2.1)–(2.5) and $u_I$ be the interpolation of $u$ in the IFE space $V_{h,0}$. If $u \in H^1(\Omega) \cap H^3(\Omega^- \cup \Omega^+) \cap W^{2,\infty}(\Omega^- \cup \Omega^+)$ then for all $v_h \in V_{h,0}$

$$
 a_h(u - u_I, v_h) \leq C \left( h^{1+\rho} \left( \|u\|_{3,\Omega^- \cup \Omega^+} + \|u\|_{2,\infty,\Omega^- \cup \Omega^+} \right) + Ch^{1.5} \|u\|_{2,\infty,\Omega^- \cup \Omega^+} \right) \|v_h\|_h, \tag{3.2}
$$

where $C$ is a constant independent of interface location and $h$ and $\rho = \min(\alpha, \frac{\sigma}{2}, \frac{1}{2})$. 

Downloaded from https://academic.oup.com/imajna/article-abstract/38/4/2123/4108202 by guest on 13 January 2019
Proof. Notice that

\[ a_h(u - u_I, v_h) = \sum_{T \in \mathcal{T}_h} \int_T \beta \nabla (u - u_I) \cdot \nabla v_h \, dx - \sum_{e \in \mathcal{E}_h^i} \int_e \{ \beta \nabla (u - u_I) \cdot n_e \} [v_h] \, ds \]

\[ + \varepsilon \sum_{e \in \mathcal{E}_h^i} \int_e \{ \beta \nabla v_h \cdot n_e \} [u - u_I] \, ds + \sum_{e \in \mathcal{E}_h^i} \int_e \frac{\sigma_0}{|e|} [u - u_I] [v_h] \, ds \]

\[ = \sum_{T \in \mathcal{T}_h^+} \int_T \beta \nabla (u - u_I) \cdot \nabla v_h \, dx + \sum_{T \in \mathcal{T}_h^-} \int_T \beta \nabla (u - u_I) \cdot \nabla v_h \, dx \]

\[ + \sum_{T \in \mathcal{T}_h^i} \int_T \beta \nabla (u - u_I) \cdot \nabla v_h \, dx - \sum_{e \in \mathcal{E}_h^i} \int_e \{ \beta \nabla (u - u_I) \cdot n_e \} [v_h] \, ds \]

\[ + \varepsilon \sum_{e \in \mathcal{E}_h^i} \int_e \{ \beta \nabla v_h \cdot n_e \} [u - u_I] \, ds + \sum_{e \in \mathcal{E}_h^i} \int_e \frac{\sigma_0}{|e|} [u - u_I] [v_h] \, ds \]

\[ = I_1 + I_2 + I_3 + I_4 + I_5 + I_6. \quad (3.3) \]

Since \( \mathcal{T}_h \) satisfies Condition \((\sigma, \alpha)\), it follows that \( \mathcal{T}_h^+ \) and \( \mathcal{T}_h^- \) also satisfy the Condition \((\sigma, \alpha)\). Using the fact that the IFE functions becoming standard linear functions on regular elements, we have the following estimates for \( I_1 \) and \( I_2 \), whose proof can be found in Xu & Zhang (2004):

\[ |I_1| \leq Ch^{1+\rho}(\|u\|_{3,\Omega} + \|u\|_{2,\infty,\Omega})|v_h|_h, \quad (3.4) \]

\[ |I_2| \leq Ch^{1+\rho}(\|u\|_{3,\Omega} + \|u\|_{2,\infty,\Omega})|v_h|_h, \quad (3.5) \]

where \( C \) is a constant independent of the location of the interface and mesh size \( h \) and \( \rho = \min(\alpha, \frac{\sigma_2}{2}, \frac{1}{2}) \).

Now we proceed to estimate \( I_3 \). By the Cauchy–Schwartz inequality, we have

\[ I_3 = \sum_{T \in \mathcal{T}_h^i} \int_T \beta \nabla (u - u_I) \cdot \nabla v_h \, dx \]

\[ \leq \left( \sum_{T \in \mathcal{T}_h^i} \|\beta^{1/2} \nabla (u - u_I)\|_{0,T}^2 \right)^{1/2} \left( \sum_{T \in \mathcal{T}_h^i} \|\nabla v_h\|^2_{0,T} \right)^{1/2} \]

\[ \leq \left( \sum_{T \in \mathcal{T}_h^i} \max(\beta^-, \beta^+) \|\nabla (u - u_I)\|_{0,T}^2 \right)^{1/2} \left( \sum_{T \in \mathcal{T}_h^i} \|\beta^{1/2} \nabla v_h\|^2_{0,T} \right)^{1/2} \]

\[ \leq C \left( \sum_{T \in \mathcal{T}_h^i} h^2 \|u\|_{2,T^- \cup T^+}^2 \right)^{1/2} \left( \sum_{T \in \mathcal{T}_h^i} \|\beta^{1/2} \nabla v_h\|^2_{0,T} \right)^{1/2} \]
\[
\sum_{T \in \mathcal{T}_h^i} \frac{1}{\epsilon} \left\{ \beta \nabla (u - u_I) \cdot n_e \right\} [v_h] ds
\]
\[
\leq \left( \sum_{e \in \mathcal{E}_h^i} \frac{1}{\epsilon} \left[ \frac{\beta}{\sigma_e^0} \left\{ \nabla (u - u_I) \cdot n_e \right\}^2 ds \right] \right)^{1/2} \left( \sum_{e \in \mathcal{E}_h^i} \frac{1}{\epsilon} [v_h]^2 ds \right)^{1/2}
\]
\[
\leq C h^{1/2} \left( \sum_{e \in \mathcal{E}_h^i} \frac{1}{\epsilon} \left[ \beta \nabla (u - u_I) \cdot n_e \right]^2 ds \right)^{1/2} \left( \sum_{e \in \mathcal{E}_h^i} \frac{1}{\epsilon} [v_h]^2 ds \right)^{1/2}
\]
\[
\leq C h^{3/2} \|u\|_{2, \infty, \Omega^- \cup \Omega^+} \left( \sum_{T \in \mathcal{T}_h} \frac{1}{\epsilon} \left[ v_h \right]^2 ds \right)^{1/2}
\]
\[
\leq C h^{3/2} \|u\|_{2, \infty, \Omega^- \cup \Omega^+} \|v_h\|_h,
\]

where we have used (4.19) in Lin et al. (2015). To bound \( I_5 \), we use the standard trace inequality (Ciarlet, 2002; Brenner & Scott, 2008), because \((u - u_I)|_{T_i}\) is a function in \( H^1(T_i) \) and consider only the trace of \( u - u_I \), for which we have

\[
\|[u - u_I]\|_{0, \epsilon} \leq \|[u - u_I]|_{T_{e,1}}\|_{0, \epsilon} + \|(u - u_I)|_{T_{e,2}}\|_{0, \epsilon}
\]
\[
\leq C h^{-1/2} \left( \|u - u_I\|_{0, \epsilon, 1} + h \|\nabla (u - u_I)\|_{0, \epsilon, 1} \right)
+ C h^{-1/2} \left( \|u - u_I\|_{0, \epsilon, 2} + h \|\nabla (u - u_I)\|_{0, \epsilon, 2} \right)
\]
\[
\leq C h^{3/2} \left( \|u\|_{2, \infty, \Omega^- \cup T_{e,1}^+} + \|u\|_{2, \infty, \Omega^- \cup T_{e,2}^+} \right)
\]
\[
\leq C h^{3/2} \|u\|_{2, \infty, \Omega^- \cup \Omega^+}.
\]
Also, the trace inequality for IFE function (2.19) implies that

\[ \| \{ \beta \nabla v_h \cdot n_e \} \|_{0,e} \leq \| \{ \beta \nabla v_h \vert_{Te,1} \cdot n_e \} \|_{0,e} + \| \{ \beta \nabla v_h \vert_{Te,2} \cdot n_e \} \|_{0,e} \]

\[ \leq Ch^{-1/2} \left( \| \sqrt{\beta} \nabla v_h \|_{0,Te,1} + \| \sqrt{\beta} \nabla v_h \|_{0,Te,2} \right). \] (3.9)

Hence, we get

\[ I_5 = \left| \sum_{e \in E_h^I} \int_{e} \{ \beta \nabla v_h \cdot n_e \} [u - u_I] \, ds \right| \]

\[ \leq \left( \sum_{e \in E_h^I} \| \{ \beta \nabla v_h \cdot n_e \} \|_{0,e}^2 \right)^{1/2} \left( \sum_{e \in E_h^I} \| [u - u_I] \|_{0,e}^2 \right)^{1/2} \]

\[ \leq C \left( \sum_{e \in E_h^I} h^{-1} \left( \| \sqrt{\beta} \nabla v_h \|_{0,Te,1} + \| \sqrt{\beta} \nabla v_h \|_{0,Te,2} \right)^2 \right)^{1/2} \left( \sum_{e \in E_h^I} h^3 \| u \|_{2,\infty,\Omega^- \cup \Omega^+}^2 \right)^{1/2} \]

\[ \leq Ch^2 \| u \|_{2,\infty,\Omega^- \cup \Omega^+} \left( \sum_{T \in T_h^I} \| \sqrt{\beta} \nabla v_h \|_{0,T}^2 \right)^{1/2} \left( \sum_{T \in T_h^I} 1 \right)^{1/2} \]

\[ \leq Ch^{3/2} \| u \|_{2,\infty,\Omega^- \cup \Omega^+} \| v_h \|_h, \] (3.10)

where we have also used the fact \( \sum_{T \in T_h^I} 1 \approx O(h^{-1}) \). For \( I_6 \), by the Cauchy–Schwarz inequality and (3.8), we have

\[ I_6 = \sum_{e \in E_h^I} \int_{e} \frac{\sigma^0_0}{|e|} [u - u_I] [v_h] \, ds \]

\[ \leq \left( \sum_{e \in E_h^I} \int_{e} \frac{\sigma^0_0}{|e|} [u - u_I] \, ds \right)^{1/2} \left( \sum_{e \in E_h^I} \int_{e} \frac{\sigma^0_0}{|e|} [v_h] \, ds \right)^{1/2} \]

\[ \leq Ch^{-1/2} \left( \sum_{e \in E_h^I} \| [u - u_I] \|_{0,e}^2 \right)^{1/2} \| v_h \|_h \]

\[ \leq Ch^2 \| u \|_{2,\infty,\Omega^- \cup \Omega^+} \left( \sum_{T \in T_h^I} 1 \right)^{1/2} \| v_h \|_h \]

\[ \leq Ch^{3/2} \| u \|_{2,\infty,\Omega^- \cup \Omega^+} \| v_h \|_h, \] (3.11)
where we have also used the fact $\sum_{T \in T_h} 1 \approx O(h^{-1})$. Summarizing the bounds for $I_i$ ($i = 1, 2, \cdots, 6$) together gives (3.2).

**Remark 3.4** When the discontinuity disappears, $e_h^i$ will become empty. In that case, $I_i$ ($i = 3, 4, 5, 6$) will become zero, and we can reproduce the standard supercloseness result (Xu & Zhang, 2004).

**Remark 3.5** Here, we only discuss the triangle element. For the bilinear PPIFE methods, we can prove similar supercloseness results by adapting the integral identities in Lin et al. (1991) and Lin & Yan (1996), the trace inequalities for bilinear IFE functions (Lin et al., 2015) and the same techniques that we used here to deal with the interface part.

Based on the supercloseness results, we can prove the following theorem:

**Theorem 3.6** Assume the same hypothesis in Theorem 3.3 and let $u_h$ be the IFE solution of discrete variational problem (2.20); then

$$\|u_h - u_I\|_h \leq C \left( h^{1+\rho}(\|u\|_{3,\Omega^+\cup\Omega^-} + \|u\|_{2,\infty,\Omega^+\cup\Omega^-}) + Ch^{3/2}\|u\|_{2,\infty,\Omega^+\cup\Omega^-} \right),$$

(3.12)

where $\rho = \min(\alpha, \sigma^2, 1/2)$.

**Proof.** Since $V_{h,0}$ is a subset of $X_{h,0}$, it follows that

$$a_h(u - u_h, v_h) = 0 \quad \text{for all } v_h \in V_{h,0}.$$  

(3.13)

Then, we have

$$a_h(u_h - u_I, v_h) = a_h(u - u_I, v_h) \quad \text{for all } v_h \in V_{h,0}.$$  

(3.14)

Taking $v_h = u_h - u_I$ and using Theorem 3.3 and Lemma 2.2, we prove (3.12). \qed

**Remark 3.7** Similarly as Remark 3.4, when the discontinuity disappears, (3.12) will reduce to the standard supercloseness result (Xu & Zhang, 2004).

### 3.2 Superconvergence results

In this subsection, using the supercloseness results, we show that the recovered gradient of the PPIFE solution is superconvergent to the exact gradient.

To define the gradient recovery operator introduced (Guo & Yang, 2017), we first generate a local body-fitted mesh $\hat{T}_h$, by adding some new vertices into $N_h$ (Li et al., 2003; Guo & Yang, 2017). Here, the body-fitted mesh means that the triangulation $\hat{T}_h$ is aligned with the interface, assuming that $\hat{S}_h$ is the $C^0$ linear finite element space defined on $\hat{T}_h$.

Let $\hat{N}_h$ denote all vertices in $\hat{T}_h$, and one has $N_h \subset \hat{N}_h$. For any $z \in \hat{N}_h$, let $\hat{T}_z$ denote the set of all triangles in $\hat{T}_h$ having $z$ as their vertex and define

$$\langle E_h v \rangle(z) = \frac{1}{|\mathcal{T}_z|} \sum_{\hat{T} \in \mathcal{T}_z} v_\hat{T}(z),$$

(3.15)
with $|\hat{T}_h|$ being the cardinality of $\hat{T}_h$ and $v_\Gamma = v|_\Gamma$. We can define $E_hv$ on $\Omega$ by standard linear finite element interpolation in $S_h$ after obtaining the values $(E_hv)(z)$ at all vertices.

Let $\Gamma_h$ be the approximated interface by connecting the intersection points of edges with $\Gamma$. We can category the triangulation $\hat{T}_h$ into the following two disjoint sets:

$$\hat{T}_h^- := \{ T \in T_h | \text{all three vertices of } T \text{ are in } \Omega^- \},$$

$$\hat{T}_h^+ := \{ T \in T_h | \text{all three vertices of } T \text{ are in } \Omega^+ \}. \quad (3.16)$$

Let $\Omega_h^- = \bigcup_{T \in \hat{T}_h^+} T$ and $\Omega_h^+ = \bigcup_{T \in \hat{T}_h^-} T$. Suppose $\hat{S}_h^-$ and $\hat{S}_h^+$ are the continuous linear finite element spaces defined on $\hat{T}_h^-$ and $\hat{T}_h^+$, respectively.

Denote the PPR gradient recovery operator on $\hat{S}_h$ by $G_h^-$ (Zhang & Naga, 2005). Note that $G_h^- v_h^-$ is a finite element vector-valued function in $\hat{S}_h^- \times \hat{S}_h^-$ for any given finite element function $v_h^-$ $\in$ $\hat{S}_h^-$. To define the recovered gradient $G_h^- v_h^-$, it suffices to define $G_h^- v_h^-$ at every nodal point. Let $\hat{N}_h^-$ denote the set of all nodal points of $\hat{T}_h^-$. For any vertex $z \in \hat{N}_h^-$, let $\hat{K}_h^-$ be a patch of elements in $\hat{T}_h^-$ around $z$. The readers are referred to Zhang & Naga (2005), Naga & Zhang (2004) and Guo et al. (2016) for the construction of the local patch of elements $\hat{K}_h^-$. Select all nodes in $\hat{N}_h^- \cap (\hat{S}_h^- \cup \hat{K}_h^-)$ as sampling points and fit a polynomial $p_z \in P_{k+1}(\hat{K}_h^-)$ in the least square sense at those sampling points, i.e.,

$$p_z = \arg \min_{p \in P_{k+1}(\hat{K}_h^-)} \sum_{z \in \hat{N}_h^- \cap (\hat{S}_h^- \cup \hat{K}_h^-)} (u_h - p)^2(\tilde{z}). \quad (3.18)$$

Then, the recovered gradient at $z$ is defined as

$$(G_h^- u_h)(z) = \nabla p_z(z).$$

The gradient recovery operator $G_h^-$ is a bounded operator in the sense of

$$\|G_h^- v_h^-\|_{0,\Omega} \leq C \|v^-\|_{0,\Omega^-}, \quad (3.19)$$

with $C$ being a constant independent of the mesh size $h$ and the solution $u$.

Similarly, we can define the PPR gradient recovery operator $G_h^+$ from $\hat{S}_h^+$ to $\hat{S}_h^+ \times \hat{S}_h^+$. Then, for any $u_h \in V_h$, let $G_h^+ : \hat{S}_h \rightarrow (\hat{S}_h^- \cup \hat{S}_h^+) \times (\hat{S}_h^- \cup \hat{S}_h^+)$ be the IPPR operator proposed in Guo & Yang (2016), which is defined as the following:

$$(G_h^+ u_h)(z) = \begin{cases} (G_h^- u_h)(z), & \text{if } z \in \Omega_h^-, \\ (G_h^+ u_h)(z), & \text{if } z \in \Omega_h^+. \end{cases} \quad (3.20)$$

Then, the recovered gradient of PPIFE solution $u_h$ is defined as

$$R_h u_h = G_h^+(E_hv_h). \quad (3.21)$$

The linear boundedness and consistency of the gradient recovery operator $R_h$ are shown in Guo & Yang (2017). The previous established supercloseness result enables us to prove the following main superconvergence result:
Theorem 3.8 Assume the same hypothesis in Theorem 3.3, and let $u_h$ be the IFE solution of discrete variational problem (2.20). Then,

$$
\|\nabla u - R_h u_h\|_{0,\Omega} \leq C \left( h^{1+\rho} (\|u\|_{3,\Omega^+ \cup \Omega^-} + \|u\|_{2,\infty,\Omega^+ \cup \Omega^-}) + C h^{1.5} \|u\|_{2,\infty,\Omega^+ \cup \Omega^-} \right). \tag{3.22}
$$

Proof. We decompose $\nabla u - R_h u_h$ as $(\nabla u - R_h u_I) - (R_h u_I - R_h u_h)$. Then, the triangle inequality implies that

$$
\|\nabla u - R_h u_h\|_{0,\Omega} \leq \|\nabla u - R_h u_I\|_{0,\Omega} + \|R_h u_I - R_h u_h\|_{0,\Omega} := I_1 + I_2. \tag{3.23}
$$

According to Theorem 3.7 in Guo & Yang (2017), we have

$$
I_1 \lesssim h^2 \|u\|_{3,\Omega^+ \cup \Omega^-}. \tag{3.24}
$$

Using definition (3.21), we obtain that

$$
I_2 = \|G_h E_h (u_I - u_h)\|_{0,\Omega} \lesssim \|G_h E_h (u_I - u_h)\|_{0,\Omega^-} + \|G_h E_h (u_I - u_h)\|_{0,\Omega^+}.
$$

$$
\lesssim \|\nabla E_h (u_I - u_h)\|_{0,\Omega^-} + \|\nabla E_h (u_I - u_h)\|_{0,\Omega^+} \lesssim \|\nabla (u_I - u_h)\|_{0,\Omega} \lesssim h^{1+\rho} (\|u\|_{3,\Omega^+ \cup \Omega^-} + \|u\|_{2,\infty,\Omega^+ \cup \Omega^-}) + C h^{3/2} \|u\|_{2,\infty,\Omega^+ \cup \Omega^-}, \tag{3.25}
$$

where we have used the boundedness property of $G_h^\pm$ in the second inequality, Corollary 3.4 of Guo & Yang (2017) in the fourth inequality and Theorem 3.6 in the last inequality. Combining (3.23)–(3.25) completes the proof of (3.22). □

The gradient recovery operator $R_h$ naturally provides an a posteriori error estimator for the PPIFE method. We define a local a posteriori error estimator on element $T \in T_h$ as

$$
\eta_T = \begin{cases}
\|\beta^{1/2} (R_h u_h - \nabla u_h)\|_{0,T} & \text{if } T \in T_h^r, \\
\left( \sum_{\tilde{T} \subset T, \tilde{T} \in T_h} \|\beta^{1/2} (R_h u_h - \nabla u_h)\|_{0,\tilde{T}}^2 \right)^{1/2} & \text{if } T \in T_h^i, 
\end{cases} \tag{3.26}
$$

and the corresponding global error estimator as

$$
\eta_h = \left( \sum_{T \in T_h} \eta_T^2 \right)^{1/2}. \tag{3.27}
$$

With the above superconvergence result, we are ready to prove the asymptotic exactness of error estimators based on the recovery operator $R_h$. 

Theorem 3.9  Assume the same hypothesis in Theorem 3.3 and let \( u_h \) be the IFE solution of discrete variational problem (2.20). Further assume that there is a constant \( C(u) > 0 \), such that

\[
\| \nabla (u - u_h) \|_{0, \Omega} \geq C(u) h. \tag{3.28}
\]

Then, it holds that

\[
\left| \frac{\eta_h}{\| \beta^{1/2} \nabla (u - u_h) \|_{0, \Omega}} - 1 \right| \leq Ch^\rho. \tag{3.29}
\]

Proof. By the Triangle inequality, Theorem 3.8 and Theorem (3.28), we have

\[
\left| \frac{\eta_h}{\| \beta^{1/2} \nabla (u - u_h) \|_{0, \Omega}} - 1 \right| \leq \frac{\| \beta^{1/2} (R_h u_h - \nabla u_h) \|_{0, \Omega}}{\| \beta^{1/2} \nabla (u - u_h) \|_{0, \Omega}} \leq \frac{Ch^{1+\rho} (\| u \|_{3, \Omega^-} + \| u \|_{2, \infty, \Omega^-} + \| u \|_{3, \Omega^+} + \| u \|_{2, \infty, \Omega^+})}{\min(\beta^+, \beta^-) c(u) h} \leq Ch^\rho.
\]

\[\square\]

Remark 3.10  Assumption 3.28 is reasonable on general shape-regular meshes by the lower bounds of the approximation error by piecewise polynomials (Lin et al., 2014).

Remark 3.11  Theorem 3.9 implies that (3.26) (or (3.27)) is an asymptotically exact a posteriori error estimator for PPIFE methods.

4. Numerical examples

In this section, the previously established supercloseness and superconvergence theory are demonstrated by three numerical examples. The first two are benchmark problems for testing the numerical methods for linear interface problem. For these two examples, the computational domain are chosen as \( \Omega = [-1, 1] \times [-1, 1] \). The uniform triangulation of \( \Omega \) is obtained by dividing \( \Omega \) into \( N^2 \) sub-squares and then dividing each sub-square into two right triangles. The resulting uniform mesh size is \( h = 1/N \). The last example is a nonlinear interface problem. We test the examples using three different PPIFE methods (Lin et al., 2015): the symmetric PPIFE method (SPPIFEM), incomplete PPIFE method (IPPIFEM) and nonsymmetric PPIFE method (NPPIFEM), which are corresponding to \( \epsilon = -1 \), \( \epsilon = 0 \) and \( \epsilon = 1 \), respectively. We choose the penalty parameter \( \sigma_0^\epsilon = \sqrt{\max(\beta^-, \beta^+)} \) for SPPIFEM and IPPIFEM, and \( \sigma_0^0 = 1 \) for NPPIFEM. For convenience, we shall adopt the following error norms in all the examples:

\[
D_e := \| \nabla (u - u_h) \|_{0, \Omega}, \quad D' e := \| \nabla u_I - \nabla u_h \|_{0, \Omega}, \quad D'' e := \| \nabla u - R_h u_h \|_{0, \Omega}.
\tag{4.1}
\]

Example 4.1  In this example, we consider the elliptic interface problem (2.1) with a circular interface of radius \( r_0 = \frac{\pi}{6} \) as studied in Li et al. (2003). The exact solution is

\[
u(z) = \begin{cases} 
\frac{z^3}{\beta^-}, & \text{if } z \in \Omega_-, \\
\frac{z^3}{\beta^+} + \left( \frac{1}{\beta^-} - \frac{1}{\beta^+} \right) r_0^3, & \text{if } z \in \Omega^+,
\end{cases}
\]

where \( r = \sqrt{x^2 + y^2} \).
We use two typical jump ratios: $\beta^-/\beta^+ = 1/10$ and $\beta^-/\beta^+ = 1/1000000$. Tables 1–6 report numerical results. For $De$, all three partially penalized finite element methods converge with the optimal rate $O(h)$ for both differential jump ratios. As for $D^e$ and $D'^e$, $O(h^{1.5})$ order of convergence can be clearly observed for all cases, which support our Theorems 3.3 and 3.4.

We also test the case with jump ratio $\beta^-/\beta^+ = 1/1000000$. The numerical result for SPPIFEM is listed in Table 7. The supercloseness result and superconvergent rate can be also observed in Table 7.

Example 4.2 In this example, we consider the interface problem (2.1) with a cardioid interface as in Hou & Liu (2005). The interface curve $\Gamma$ is the zero level of the function

$$\phi(x, y) = (3(x^2 + y^2) - x)^2 - x^2 - y^2,$$

as shown in Fig. 2. We choose the exact solution $u(x, y) = \phi(x, y)/\beta(x, y)$, where

$$\beta(x, y) = \begin{cases} 
xy + 3, & \text{if } (x, y) \in \Omega^-, \\
100, & \text{if } (x, y) \in \Omega^+. 
\end{cases}$$

Fig. 2. Shape of interface for Example 4.2.

Note that the interface is not Lipschitz continuous and has a singular point at the origin. Tables 8–10 display the numerical data. We observe the same supercloseness and superconvergence phenomena as predicted by our theory.

**Example 4.3** In this example, we consider the following nonlinear interface problem

$$-\nabla \cdot (\beta(z)\nabla u(z)) + \sin(u(z)) = f(z), \quad z \in \Omega \setminus \Gamma,$$

with homogeneous jump conditions (2.4) and (2.5), where $\Omega = [-2, 2] \times [-2, 2] \setminus [-0.5, 0.5] \times [-0.5, 0.5].$ The interface curve $\Gamma$ is circle centered at origin with radius $r_0 = \pi/3.$ The exact solution is

$$u(z) = \begin{cases} \frac{\log(r)}{\beta^-}, & \text{if } z \in \Omega_-, \\ \frac{\log(r)}{\beta^+} + \left(1 - \frac{1}{\beta^+}\right) \log(r_0), & \text{if } z \in \Omega^+, \end{cases}$$
where \( r = |z| = \sqrt{x^2 + y^2} \). The right-hand side function \( f \) and boundary condition are obtained from the exact solution.

The nonlinear interface problem is solved by the PPIFE method with Newton’s iteration on a series of uniform meshes. The coarsest mesh is depicted in Fig. 3 and the finer meshes are obtained by the uniform refinement. Numerical results are reported in Tables 11–13. We observe the same superconvergence and supercloseness phenomena as linear problems.

5. Conclusion

In this article, we study the superconvergence theory for PPIFE methods. Specifically, we obtain supercloseness results analogous to standard linear finite element method. Due to the existence of the interface, we can only prove a supercloseness result of order $O(h^{1.5})$. We also notice that the supercloseness result will reduce to the well-known one for the standard linear element when the discontinuity disappears. These results provide us with a fundamental tool to prove the $O(h^{1.5})$ superconvergence of recovered gradient using the gradient recovery operator proposed in Guo & Yang (2017). We present three numerical examples to support our theoretical results.
